

# GTR22b: Key priorities (high level)

February 28<sup>th</sup>, 2024

# Summary on Heavy Duty Industry specifics

- Electric HDVs in the EU fleet is significantly lower than for LDV (**0.1% market share 2022**). To allow industry to be competitive (conventional drive-train) with battery technology on the EU HDV and move towards decarbonisation targets needs to be reflected in regulations.
  - Commercial vehicle business has an **almost infinite number of tailor-made vehicles** that can be built using a number of building blocks
  - Applying the same strategy for type approval testing as is used for GTR22a for light-duty/passenger vehicles would create an enormous testing burden for low volumes for all HDV manufacturers and must be avoided.
  - **In principle, LDV manufacturers develop a few variants but manufacture them in very large volumes. HDV manufacturer, on the other hand, develop an enormous amount of variants but only sell a few per variant.**
  - **Scalability(component-based TA and calculation/verification for vehicle UBC/E<sub>certified</sub>) is of high importance for HDV industry, similar to the VECTO-type approval process**
- **The following slides shall show why we need a dedicated workshop to work out all the complex details on a feasible HDV Battery Durability GTR22b**

# Procedure: Metrics and References

## Challenges

### Method 2: BIDI

- availability of in-vehicle technology; availability of testing equipment and facilities

### Method 1a,b: on-road

- external equipment installation and accuracy

### Alternative: Chassis-Dyno

- availability in cps like USA, JP and Europe (vehicles above 7,5t)

## Pros

### Method 2: BIDI

- controlled environment; easy on-board verification with calibrated external bidi-charger on defined testing environment (non-invasive)

### Method 1a,b: on-road

- Suitable for all vehicles (Bidi criteria missing)

### Alternative: Chassis-Dyno

- controlled environment; easy on-board verification with external equipment from test rig (non-invasive)

## Solution

### Method 2: BIDI

- alternative test methods 1a, 1b during phase of low market maturity

### Method 1a,b: on-road

- Part A: accuracy determination based on type approval

### Alternative: Chassis-Dyno

- alternative test method for 1a, 1b and 2

- OICA is still in favor of referring to UBC charged, as shown in our measurements and assessments
- However, if UBE will be the reference, scattered boundary conditions could lead to a fail decision
- With UBC as reference, charge and discharge are equal

# Additional metric for MPR assessment

## Installed system capacity must be considered for the lifetime requirements

Range criteria: 700,000 km

Assumption:

**Energy consumption of vehicle 1 kWh/km**  
(flat test track, no hills!)

Total energy  
consumption  
of vehicle  
700,000 kWh

Energy provided per Pack:

2 Pack conf.:

$$700,000\text{kWh} / 2 = 350 \text{ MWh}$$

3 Pack conf.:

$$700,000\text{kWh} / 3 = 233 \text{ MWh}$$

4 Pack conf.:

$$700,000\text{kWh} / 4 = 175 \text{ MWh}$$

**Battery Pack:**  
Nominal Voltage: 670 V  
Nominal Capacity: 130 Ah  
Nominal Energy: 87 kWh

Given same installed total kWh per vehicle,  
pack specific energy throughput and thus  
aging decreases with amount of packs

**Vehicle range** based counter index for in vehicle battery durability leads to different durability criteria for identical battery packs. This would lead to a decreasing number of customer options and would favor cost and resource intensive vehicle configurations (smaller and more packs).

**Capacity/Energy throughput** based on installed battery energy or expressed by **Full Cycle Equivalent** shall be discussed within a technical workshop.

### Key items

- For HDV applications, currently proposed MPR placeholders lack an important metric: energy throughput (5.2 Battery Performance Requirements)
- Other to LDV, HDV will have stand-still or vocational power out-and input
- Therefore OICA proposes to introduce this additional metric to verify the vehicle status

# Workshop with drafting coordinator

## Family Concepts

### One battery pack - many applications

- C1: 95% DOD
- C2: 90% DOD
- C3: 85% DOD

C1-C3: are different capacity options of the same type of battery pack

#### Huge testing burden:

According to the draft legislation, in this example 12 vehicle type approval tests are needed in order for any vehicle to be chosen for part A verification. In reality, it is more complex than this.

## Procedure & Boundaries

### Methods for Checking Battery Durability Monitor for HDV

HDV with no bidirectional charging				HDV with bidirectional charging	
Method 1a	Method 1b	Method 1c	Method 1d	Method 2	
Description	charge/discharge	charge procedure	Discharge with standard	charge/discharge	

## Metrics' Effects

test Nr.	route	charge
1	flat 10,5t	fast
2	flat 10,5t	fast
3	flat 10,5t	mobile
4	hilly 39t	fast
5	hilly 39t	mobile
6*	hilly 39t	fast
7**	hilly 39t	mobile

\* Driving mode „Range“

\*\* charging aborted

- OICA made measurements, assessed the draft GTR22b versions and evaluated potential effects of its elements
- We are convinced, that such complex procedure for the highly ambitious HDV segment we will need an face-2-face deep dive technical exchange and discussion with drafting coordinator. We are proposing a two day meeting after 69th EVE.**
- A second workshop might be necessary to address details on SOCC/E reporting and Monitoring phase
