## 1 Introduction

Driving conditions have a large influence on particle generation for brake and tyre/road wear processes. From the survey of the available literature it appears that different driving conditions in experimental investigation of particle emissions from brake and tyre/road wear is one of the reasons why different - or even sometimes- contradictory conclusions are reported. In particular, during hard accelerations or decelerations ultrafine particles can be generated due to the high temperatures reached in brakes and tyres. The question is whether these conditions are within the range of the driving conditions that can be considered "normal/typical" or should be considered as "extreme" with a low occurrence frequency.
In order to harmonize future studies on particles from brake and tyre/road wear and improve the comparability of the relative results, the investigation of "normal" or "typical" driving patterns and in particular of typical accelerations/decelerations has been identified by PMP group as an important aspect to address.

The proposed approach is to use activity data collected in the framework of other projects in order to investigate typical acceleration / deceleration frequency distributions. The main objectives of this activity are to compare "typical/normal driving conditions" derived by existing datasets like the WLTP vehicle activity database with the industry standards, as well as to reach, if possible, a shared definition of normal, severe, extreme or infrequent conditions. This will narrow down the range of driving conditions to be taken into consideration as far as non-exhaust particle emissions are concerned and will improve the comparability of future studies.

This report is a summary of the full report prepared by H.S. Data Analysis and Consultancy on behalf of the JRC. It briefly describes the main results of a detailed analysis of the WLTP vehicle activity dataset. The full report is available upon request.

## 2 Description of the WLTP database

The WLTP in-use driving behaviour database consists of vehicle activity data from five different regions in the world (see Table 1). The data from Europe and the major part of the US data is customer data (i.e. real world data recorded during the actual use of the vehicle by the drivers) and thus reflects the practical use of the vehicles in real traffic. Data coming from India, Japan and Korea are not customer data. In these countries vehicles, routes and driving times were chosen in order to reflect "representative" driving.

| Region | Mileage [km] | Duration [h] | Short Trips [\#] |
| :---: | :---: | :---: | :---: |
| Europe | 432,572 | 8,003 | 200,813 |
| India | 73,694 | 1,824 | 17,358 |
| Japan | 49,868 | 1,255 | 55,944 |
| Korea | 32,399 | 790 | 26,972 |
| USA | 155,160 | 2,557 | 65,551 |
| Total | $\mathbf{7 4 3 , 6 9 4}$ | $\mathbf{1 4 , 4 3 0}$ | $\mathbf{3 6 6 , 6 3 8}$ |

Table 1: Overview of the WLTP in-use driving behaviour database
The European data was collected in Belgium, France, Germany, Italy, Poland, Slovenia, Spain, Sweden and UK. The total number of vehicles used was 146. The US customer data was collected in Atlanta, Denver, Los Angeles, San Diego and San Francisco. The number of
vehicle models was 5 . Information regarding the technical data of the vehicles is given in Table A1 to Table A4 of the Annex.

The dataset includes vehicle speed, engine speed (not for all vehicles), date and time of the day and trip number with a sample rate of 1 Hz . The acceleration was calculated using the following two approaches:

- $a_{i}=\left(v_{i+1}-v_{i}\right) / 3.6$
- $a_{i}=\left(v_{i+1}-v_{i-1}\right) / 2 / 3.6$

The second approach was used for the further analysis within the WLTP development work.
The following indicators were taken into account for the analysis:

- Short trip number within a trip (short trip = consecutive datasets with $v>=1 \mathrm{~km} / \mathrm{h}$ ),
- Acceleration (consecutive datasets with $\mathrm{a}>0.1389 \mathrm{~m} / \mathrm{s}^{2}$ ),
- Deceleration (consecutive datasets with $a<-0.1389 \mathrm{~m} / \mathrm{s}^{2}$ ),
- Cruise (consecutive datasets with $-0.1389 \mathrm{~m} / \mathrm{s}^{2}<=\mathrm{a}<=0.1389 \mathrm{~m} / \mathrm{s}^{2}$ ).

## 3 Mileage statistics

The total mileage of the trips included in the dataset is almost $800,000 \mathrm{~km} .4 .7 \%$ of this mileage is related to trips with a length below 3 km . These trips were disregarded for the analysis of acceleration and deceleration distributions. Another $5.8 \%$ of the total mileage belongs to trips with faulty sections (jumps in vehicle speed, etc.). This data was also excluded from the analysis. The remaining total mileage is $714,198 \mathrm{~km}$.

## 4 Overview of results and definition of extreme conditions

Table 2 (a-d) provide an overview of the most important distributions of this analysis split up into different regions and road categories. The US data could not be included in this particular part of the analysis because the available data do not allow the split into different road categories (i.e. urban, rural, motorway). However, US data were treated based on speed categories and the results are provided
Table 2 provides detailed data regarding the cumulative frequency ( $5^{\text {th }}-95^{\text {th }}$ percentile) of all parameters related to the use of brakes and tyre wear. Information regarding average vehicle speed, average acceleration and acceleration duration, average deceleration and deceleration duration, stop of the vehicle duration as well as the brake phase duration, and short trip duration is provided for different regions and road categories.
It can be seen from Table 2a that in European urban areas $95 \%$ of average speeds are lower than $60 \mathrm{~km} / \mathrm{h}$. Accelerations are rarely higher than $1.3 \mathrm{~m} / \mathrm{s}^{2}$, while decelerations are almost always lower than $1.6 \mathrm{~m} / \mathrm{s}^{2}$. Vehicles stay still for no longer than 55 s , while the duration of braking phase rarely exceeds 9 s . These conditions could be used to set the threshold beyond which the driving behaviour for a typical European urban area could be defined as "extreme". Similar thresholds can be derived from the $95^{\text {th }}$ percentiles referred to the two other types of road category (rural and motorway). Similarly, all parameters that fall in the first $5^{\text {th }}$ percentile should be considered too mild compared to typical real world driving conditions. The $50^{\text {th }}$ percentile of the distributions in European urban areas corresponds to a speed of $28.3 \mathrm{~km} / \mathrm{h}$, an acceleration of $0.32 \mathrm{~m} / \mathrm{s}^{2}$, a deceleration of $0.41 \mathrm{~m} / \mathrm{s}^{2}$ and a braking phase duration of 3.3 s . Vehicles stay still between short trips for approximately 6 s , thus reflecting typical traffic jam conditions with continuous stop and go phases.

| Europe | $\begin{aligned} & \text { cum } \\ & \text { freq } \end{aligned}$ | vehicle speed in km/h | acceleration duration in s | acceleration in $\mathrm{m} / \mathrm{s}^{\mathbf{2}}$ | deceleration duration in s | deceleration in $\mathrm{m} / \mathrm{s}^{\mathbf{2}}$ | stop <br> duration <br> (number <br> weighted) <br> in s | $\begin{array}{\|c} \hline \text { short trip } \\ \text { distance } \\ \text { (number } \\ \text { weighted) } \\ \text { in } m \end{array}$ | brake phase duration in $s$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

|  | 95\% | 60.2 | 15.1 | 1.28 | 14.5 | -1.55 | 55.0 | 3,270 | 9.0 |

Table 2a: Overview of the distributions of parameters related to non-exhaust emissions in Europe
Similarly it can be seen from Tables 2 b -d that $50^{\text {th }}$ percentile average speeds in different urban areas in Asia are rarely higher than $56.4-65.2 \mathrm{~km} / \mathrm{h}$. Also, accelerations and decelerations higher than of $0.80-1.34$ and $1.21-1.48 \mathrm{~m} / \mathrm{s}^{2}$, respectively, as well as braking phase durations higher than 7.9-10.6 s can be defined as "extreme". When looking into the distributions of the parameters in urban areas in Asia it comes out that all parameters are similar to those recorded in European urban areas except for the lower range of accelerations ( $\sim 0.8 \mathrm{~m} / \mathrm{s}^{2}$ ) that are found in India. General differences observed in India can also be attributed to the different types of vehicles (see annex) and roads.

| India | cum <br> freq | vehicle speed in km/h | acceleration duration in s | acceleration in $\mathrm{m} / \mathrm{s}^{\mathbf{2}}$ | deceleration duration in s | deceleration in $\mathrm{m} / \mathrm{s}^{\mathbf{2}}$ | stop duration (number weighted) in s | short trip distance (number weighted) in $\mathbf{m}$ | brake phase duration in s |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Table 2c: Overview of the distributions of parameters related to non-exhaust emissions in Japan
Significant differences between Europe and Asia were observed when "extreme" conditions in rural areas and motorways were investigated. Median speeds and standing duration of the vehicles exhibited the biggest difference. In general, it is noted that rural and urban areas in Asia are quite similar. On the other hand, "extreme" threshold values for accelerations, decelerations and braking phase durations were found to be quite similar between Europe and Asia. Table $2 e$ summarizes median ( $50^{\text {th }}$ percentile) and Table $2 f$ threshold ( $95^{\text {th }}$ percentile) values of all parameters for the examined regions and road categories.

| Korea | cum <br> freq | vehicle <br> speed in km/h | acceleration duration in $s$ | acceleration in $\mathrm{m} / \mathrm{s}^{\mathbf{2}}$ | deceleration duration in s | deceleration in $\mathbf{m} / \mathbf{s}^{\mathbf{2}}$ | stop duration (number weighted) in s | short trip distance (number weighted) in m | brake phase duration in s |

Table 2f: Overview of extreme distributions ( $95^{\text {th }}$ percentile) of non-exhaust related parameters worldwide

## 5 Vehicle speeds

Figure 1 shows the time weighted vehicle speed distribution curves for the different countries as well as for the different campaigns within the same country. Significant differences are observed when European and Asian data are compared, while US data seem to be closer to the European. For instance, median speeds ( $50^{\text {th }}$ percentile) of $40 \mathrm{~km} / \mathrm{h}$ are observed in Asian territories, while in some European countries (Belgium, Slovenia, Italy) median speed was higher than $50 \mathrm{~km} / \mathrm{h}$. US average speed was found to be somewhat higher than 50 $\mathrm{km} / \mathrm{h}$. In some cases significant differences are observed even within European data. For instance, the measurement campaigns in Poland and Spain are dominated by urban traffic conditions ( $90 \%$ of average speeds are lower than 65 and $85 \mathrm{~km} / \mathrm{h}$, respectively), while the campaign in Italy has a high influence of rural and motorway traffic ( $45 \%$ and $35 \%$ of average speeds are higher than 65 and $85 \mathrm{~km} / \mathrm{h}$, respectively). Furthermore, some smaller differences between the individual vehicles (drivers) within a country are also observed particularly with data coming from the Asian region.

From Figure 1 it is difficult to define a worldwide common threshold value of the speed beyond which the driving behaviour could be considered as "extreme". For instance, in India speeds higher than $65-85 \mathrm{~km} / \mathrm{h}$ fall in the range above the $95^{\text {th }}$ percentile, while for some European countries (Belgium, Italy, France, Germany) as well as for the US this threshold
speed is close to $120 \mathrm{~km} / \mathrm{h}$. For that reason it is proposed to conduct this type of investigation with data separated for the different road categories (see chapter 4 - Table 2f). On the contrary, average speeds lower than $2 \mathrm{~km} / \mathrm{h}$ could be globally considered as threshold values for too mild conditions and therefore inappropriate for studying representative real world conditions (lower $5^{\text {th }}$ percentile).

It has to be noted that data from India, Japan and Korea are not customer data, but results from well-designed measurement campaigns dedicated to be representative for these countries.

Figure 1: Time weighted speed distributions (without stop times) for the different countries
The customer datasets Belgium 1, France 1, France 2, Germany, Italy, Slovenia, UK M1, Poland and Spain came along with road category indicators for urban, rural and motorway. This way it was able to calculate the key parameters of these datasets and more specifically the parameters related to mileage, driving time and average speeds per country (Table 3).

|  | Distance share [\%] |  |  | Time share [\%] |  |  | Average Speed with stops [km/h] |  |  | Average Speed without stops [km/h] |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Country | Mot/way | Rural | Urban | Mot/way | Rural | Urban | Mot/way | Rural | Urban | Mot/way | Rural | Urban |
| Belgium | 38.1 | 50.4 | 11.5 | 21.3 | 57.1 | 21.5 | 89.6 | 44.3 | 26.9 | 92.7 | 50.4 | 32.8 |
| France 1 | 27.6 | 44.0 | 28.3 | 11.0 | 34.2 | 54.8 | 116.1 | 59.5 | 24.0 | 117.0 | 62.7 | 31.1 |

| Italy | 40.5 | 41.6 | 17.9 | 22.5 | 37.0 | 40.5 | 109.4 | 68.2 | 26.8 | 109.9 | 70.6 | 32.8 |
| Slovenia | 20.3 | 49.3 | 30.4 | 8.8 | 33.6 | 57.6 | 106.9 | 68.3 | 24.5 | 108.5 | 70.9 | 31.2 |
| UK | 3.1 | 55.2 | 41.7 | 1.3 | 35.9 | 62.7 | 100.5 | 67.1 | 29.1 | 101.5 | 68.7 | 34.1 |
| Poland | 2.5 | 32.8 | 64.7 | 0.7 | 17.1 | 82.3 | 104.3 | 55.9 | 22.9 | 105.2 | 61.0 | 30.2 |
| Spain | 10.6 | 50.7 | 38.7 | 3.0 | 25.2 | 71.8 | 112.0 | 63.9 | 17.1 | 114.0 | 66.5 | 26.5 |

Table 3: Key parameters with respect to mileage, driving time and average speeds in Europe

Indicative road category specific vehicle speed distributions for individual vehicles from France, Germany and Italy are provided in Figure 2a-c.

Figure 2: Vehicle speed distributions for different road categories in the European campaign:
a (France), b (Germany), and c (Italy)

Median speeds ( $50^{\text {th }}$ percentile) in the urban areas of the three countries ranged from 15-25 $\mathrm{km} / \mathrm{h}$, which is somewhat lower than the average European value of $28.3 \mathrm{~km} / \mathrm{h}$ (Table 2e). Higher deviations were observed in rural areas ( $60-85 \mathrm{~km} / \mathrm{h}$ ) and motorways ( $110-130 \mathrm{~km} / \mathrm{h}$ ), with however the values being within the average European speeds ( 64.7 and $114.8 \mathrm{~km} / \mathrm{h}$, respectively). Also, some differences between the individual vehicles (drivers) within a country were observed particularly for motorway data. Another conclusion from the study is that data for Belgium are quite inhomogeneous and show high percentages of saturated and/or congested traffic, especially on motorways.

## 6 Short trip and stop phase analysis

### 6.1 Stop phases

In order to assess the typical number of stops, the distances driven between the stops etc., the data was separated into stop periods and short trips. Stop periods are defined as connected time sequences with vehicle speeds below $1 \mathrm{~km} / \mathrm{h}$, short trips are connected time sequences with vehicle speeds $>=1 \mathrm{~km} / \mathrm{h}$.

Figure 2: Stop duration distributions (number weighted) for different regions
Figure 2 shows the number weighted stop phase duration distributions for different regions worldwide. Number weighted means that the percentages on the $y$-axis indicate the percentage of the whole number of stop phases with a duration that corresponds to the $x$ axis value. It can be seen that median stop phases ( $50^{\text {th }}$ percentile) in Korea and Japan are generally longer ( $\sim 20 \mathrm{~s}$ ) compared to the rest of the database ( $\sim 6 \mathrm{~s}$ ). It is clear that stop phases in Europe and the USA are not only linked with traffic lights but also with spots with intense traffic and therefore continuous use of the brakes. When trying to identify threshold values for "extreme" stop duration (i.e. $95^{\text {th }}$ percentile), the differences among regions are more pronounced. While for Europe and the US stop durations longer than 60 s could be considered as "extreme", in Korea and India only stops longer than 90 s fall in the range of $95^{\text {th }}-100^{\text {th }}$ percentile. These observations are in line with those described in chapter 4 and more particular with the information provided in Tables 2 a to 2 f .

Figure shows the number weighted stop duration distributions for Europe separated into the three road categories (i.e. urban, rural and motorway). As described in Chapter 4, vehicles in European roads stay still for no longer than 55 s , regardless the road category ( $95^{\text {th }}$
percentile). On the other hand, median stop duration in urban and rural areas is approximately 6 s , while in motorways is slightly higher ( 6.2 s ).

Figure 4: Stop duration distributions (number weighted) for different road categories

### 6.2 Short trips

Figure shows the number weighted (i.e. the value in Y axis corresponds to the percentage of the number of short trips with the value indicated in X axis out of all short trips taken into account) short trip distance distributions for different regions. Median short trip distance ( $50^{\text {th }}$ percentile) is less than 1 km worldwide, while most trips ( $95^{\text {th }}$ percentile) are not longer than 10 km at least in Europe and the US. What could be defined as "extreme" short trip distance is different only in India probably due to differences in the fleet and roads.

Figure 5: Short trip distance distributions (number weighted) for different regions
Figure 6 shows number weighted short trip distance distributions for Europe, separated for different road categories. It is not clear from the Figure but from Table 2a it is seen that median short trip distance differs significantly among the road categories, while "threshold" values are almost one order of magnitude different. In general, short trips in motorways are much longer than those of urban and rural areas.
In order to assess the occurrence of creeping situations (i.e. situations related to intense traffic or stops due to traffic lights) the short trips were binned with respect to their maximum speed and the distances were summed up per max speed bin and related to the total
distance. The results are shown for different regions in Table. Based on the assumption that the majority of trips with max speed of $5 \mathrm{~km} / \mathrm{h}$ as well as a big part of trips with max speed of $15 \mathrm{~km} / \mathrm{h}$ can be attributed to creeping situations it comes out that in Korea and the US almost $10 \%$ of the short trips are linked to intense traffic jams, while in Europe and Japan more than 1 out of 5 trips occur within a creeping situation. Finally, Table 4 shows that the average max speed of short trips in Japan (number weighted) is approximately $25 \mathrm{~km} / \mathrm{h}$, in Europe approximately $35 \mathrm{~km} / \mathrm{h}$, and in the US somewhat higher ( $\sim 45 \mathrm{~km} / \mathrm{h}$ ).

Figure 6: Short trip distance distributions for Europe separated for road categories

| Number [\#] and Share [\%] of Short trips |  |  |  |  |  |  |  |  |  |  |

| >135 | 2655 | 1.2 | 1 | 0.0 | 19 | 0.0 | 10 | 0.0 | 935 | 1.6 |

Table 4: Number and share of short trips in different max speed bins for different regions

## 7 Acceleration phases

Acceleration phases are specified as consecutive time samples with a $>0.5 \mathrm{~km} / \mathrm{h} / \mathrm{s}$ or 0.1389 $\mathrm{m} / \mathrm{s}^{2}$. In order to ease the calculation of duration and distance related distributions the results were binned for both values ( 2 s duration and 5 m distance). The analysis was performed for 3 max speeds categories: a. max speed $<=60 \mathrm{~km} / \mathrm{h}$, b. $60 \mathrm{~km} / \mathrm{h}<\max$ speed $<=80 \mathrm{~km} / \mathrm{h}$, and c. max speed $>80 \mathrm{~km} / \mathrm{h}$.

### 7.1 Duration distributions

Vehicle specific acceleration phase duration distributions for different regions worldwide for short trips with maximum speed $<=60 \mathrm{~km} / \mathrm{h}$ are shown in Figure 7a. It can be seen that the distributions are similar in all regions. For instance, the median acceleration phase duration as expressed by the $50^{\text {th }}$ percentile of the distribution varies from 3 to 5 s with most values being close to 4 s . Similarly the $95^{\text {th }}$ percentile value of the duration distribution varies from 15 to 17 s with the exception of Korea where the acceleration phase duration is higher ( 20 s ).

Figure 7: Acceleration phase duration distributions [s] for different maximum speed category worldwide: a. (<= $60 \mathrm{~km} / \mathrm{h})$, b. ( $60 \mathrm{~km} / \mathrm{h}<\max$ speed <= $80 \mathrm{~km} / \mathrm{h}$ ), and c. (> $80 \mathrm{~km} / \mathrm{h}$ )

Figure 7 b and 7 c show the corresponding distributions for acceleration phases with maximum speed between 60 and $80 \mathrm{~km} / \mathrm{h}$ and above $80 \mathrm{~km} / \mathrm{h}$, respectively. The picture here is a bit different as Japanese data are clearly "softer" compared to the average values of Europe and the US (acceleration phase duration of $\sim 2 \mathrm{~s}$ against $\sim 6 \mathrm{~s}$ ), while the US data show longer acceleration phases over the urban and rural parts of the database (i.e. speed categories with max speed under $80 \mathrm{~km} / \mathrm{h}$ ).

Figure 8 shows a comparison of the average curves for Europe with the different maximum speed ranges. It can be seen that the median acceleration phase duration for all speed categories is approximately 5 s . On the other hand, $95 \%$ of acceleration phases in urban areas last less than 14 s while for rural and motorway areas more than 20 s . These durations could be considered as threshold for extreme driving behaviour.

Class 1, 2 and 3 vehicles are vehicles with a rated power to kerb mass ratio <= $22 \mathrm{~W} / \mathrm{kg}$, between $22 \mathrm{~W} / \mathrm{kg}$ and $34 \mathrm{~W} / \mathrm{kg}$, and $>34 \mathrm{~W} / \mathrm{kg}$, respectively.

Figure 8: Acceleration phase duration distributions for short trips with different max speed

### 7.2 Distance distributions

Vehicle specific distance distributions for the different regions and for acceleration phases with max speed $<=60 \mathrm{~km} / \mathrm{h}$ are shown in Figure 9a. The median acceleration distance ( $50^{\text {th }}$ percentile) in all places is approximately 40 m with Japanese data showing once more "softer" acceleration phases (approximately 25 m ). On the other hand, acceleration distances longer than 150 m can be considered as "extreme". Once more it seems that European and US data can be treated as similar.
Figure 9b and 9c show the corresponding distributions for acceleration phases with maximum speed between 60 and $80 \mathrm{~km} / \mathrm{h}$ and above $80 \mathrm{~km} / \mathrm{h}$, respectively. Once more Japanese data seem to differ significantly both for average and threshold acceleration phase distances. The US data show this time longer acceleration phases in terms of distance covered over the rural and motorway part of the database (i.e. speed categories with max speed over $60 \mathrm{~km} / \mathrm{h}$ ).
Figure 10 shows a comparison of the average curves for Europe with the different max speed ranges. It can be seen that $95 \%$ of acceleration phases in urban areas occur within 120 m , in rural areas within 280 m and in motorway areas within 500 m . These distances could be considered as threshold for "extreme" driving behaviour.

Figure 9: Acceleration phase distance distributions [m] for different maximum speed category worldwide: $a(<=60 \mathrm{~km} / \mathrm{h}), b(60 \mathrm{~km} / \mathrm{h}<\max$ speed <= $80 \mathrm{~km} / \mathrm{h})$, and c (> $80 \mathrm{~km} / \mathrm{h}$ )

Figure 10: Acceleration phase distance distributions for short trips in Europe with different max speeds

## 8 Deceleration phases

Deceleration phases are specified as consecutive time samples with a $<-0.5 \mathrm{~km} / \mathrm{h} / \mathrm{s}$ or $0.1389 \mathrm{~m} / \mathrm{s}^{2}$. In order to ease the calculation of duration and distance related distributions the results were binned for both values ( 2 seconds for the duration and 5 m for the distance). The analysis was performed for phases up to $60 \mathrm{~km} / \mathrm{h}$, between 60 and $80 \mathrm{~km} / \mathrm{h}$ and above $80 \mathrm{~km} / \mathrm{h}$ separately.

### 8.1 Duration distributions

Vehicle specific duration distributions for the different regions and for deceleration phases with maximum speed lower than $60 \mathrm{~km} / \mathrm{h}$ are shown in Figure 11a. Deceleration phase distributions seem to be similar for all regions at least when this particular speed category is examined. The median ( $50^{\text {th }}$ percentile) deceleration phase duration varies from 3 to 5 s with most values being around 4 s . Similarly the $95^{\text {th }}$ percentile duration varies from 13 to 17 s with the most values being close to 15 s . This would practically mean that decelerations longer than 15 s could be characterized as "extreme".

Figures 11b and 11c demonstrate the corresponding distributions for deceleration phases with maximum speed between 60 and $80 \mathrm{~km} / \mathrm{h}$ and above $80 \mathrm{~km} / \mathrm{h}$. In these cases there are some differences among the regions examined with data from Japan and India pointing to shorter deceleration phases as a result to generally lower average speeds (see chapter 7). The US data show once more longer deceleration phases over the urban and rural parts of the database (i.e. speed categories with max speed under $80 \mathrm{~km} / \mathrm{h}$ ). In any case decelerations longer than 20 s could be considered as "extreme" regardless the speed category examined.
Figure 12 shows a comparison of the average curves for Europe with the different maximum speed ranges. It can be seen that $95 \%$ of deceleration phases of short trips with maximum speed lower than $60 \mathrm{~km} / \mathrm{h}$ (mostly urban related short trips) last less than 13 s , while for higher speeds the deceleration duration exceeds 20 s . Once more these durations could be considered as threshold for "extreme" driving behaviour in the European region. This assumption is confirmed from Table $2 f$ where threshold deceleration durations for all road categories are provided (14.5, 16.9 and 14.6 s for urban, rural and motorway, respectively)

Figure 11: Deceleration phase duration distributions for the different regions and different max speeds: a (<= $60 \mathrm{~km} / \mathrm{h}$ ), b ( $60 \mathrm{~km} / \mathrm{h}$ < max speed <= $80 \mathrm{~km} / \mathrm{h}$ ), and c (> $80 \mathrm{~km} / \mathrm{h}$ )

Figure 12: Deceleration phase duration distributions for short trips with different max speed

### 8.2 Distance distributions

Vehicle specific distance distributions for the different regions and for deceleration phases with max speed $<=60 \mathrm{~km} / \mathrm{h}$ are shown in Figure 13a. The median deceleration distance in all places worldwide except for Japan was found to be approximately 40 m . Deceleration distances longer than 150 m can be considered as a result of "extreme" driving behaviour. Once more, Japanese data can be considered "softer" in terms of accelerations and decelerations compared to the rest of the world. Figures 13b and 13c show the corresponding distributions for deceleration phases with max speed between 60 and $80 \mathrm{~km} / \mathrm{h}$ and above $80 \mathrm{~km} / \mathrm{h}$. Japanese data seem to differ significantly both for average and threshold deceleration phase distances, while the US data show longer deceleration phases for higher speeds.

Figure 14 shows a comparison of the average curves for Europe with the different max speed ranges. It can be seen that $95 \%$ of deceleration phases in urban areas occur within 120 m , in rural areas within 250 m and in motorway areas within 450 m . These distances could be considered as threshold for "extreme" driving behaviour.

Figure 13a: Deceleration phase duration distributions for the different regions and max speed <= $60 \mathrm{~km} / \mathrm{h}$

Figure 13: Deceleration phase duration distributions for the different regions and maximum speed categories: $b(60 \mathrm{~km} / \mathrm{h}<$ max speed <= $80 \mathrm{~km} / \mathrm{h})$ and c (> $80 \mathrm{~km} / \mathrm{h}$ )

Figure 14: Deceleration phase distance distributions for short trips with different max speeds

## 9 Phases with brake engaged

### 9.1 Determination of a speed dependent deceleration threshold curve

Another objective of the data analysis was the determination of the distributions i) of the duration of braking events and ii) of the distance covered by the vehicle during the brake use. The brake use during deceleration phases should be determined by expert guess thresholds for the deceleration. Fortunately, it was possible to use an alternative method due to the availability of in-use driving behaviour data from research project of the German Environment Agency, dedicated to the improvement of the type approval noise measurement method for light duty vehicles ("Investigations on Improving the Method of Noise Measurement for Powered Vehicles", July 1997). Within this project in-use driving behaviour measurements were performed with 11 cars in Aachen and the surroundings, where vehicle speed, engine speed and drive axle torque, but also clutch and brake engagement was measured.
Several threshold curves were tested and the resulting brake use duration and distance distributions were compared with the measured ones. The best fit was achieved for the following vehicle speed dependent deceleration threshold curve:

$$
\text { a_threshold }=-0.098468 * \ln (v)-0.30439
$$

This leads in the following polynomial function for a corresponding $v^{*}$ a threshold curve:

$$
v^{*} \text { a_threshold }=7.83392 \mathrm{E}-07^{*} v^{3}-4.10447 \mathrm{E}-04^{*} \mathrm{v}^{2}-1.80147 \mathrm{E}-01^{*} \mathrm{v}+3.35105 \mathrm{E}-01
$$

Both curves are shown in Figure 15. When vehicles with automatic transmissions are disregarded, the calculated distributions are in sufficiently good agreement with the measured distributions and therefore the proposed approach is more than satisfactory.

Figure 15: Threshold curves for the determination of brake engagement phases

### 9.2 Results for the WLTP database

### 9.2.1 Brake phase duration distributions

Vehicle specific duration distributions for the different regions and for deceleration phases with different max speed categories are shown in Figure 16.

Figure 36: Brake phase duration distributions for the different regions and maximum speed categories: a. (max speed <= $60 \mathrm{~km} / \mathrm{h}), \mathrm{b} .(60 \mathrm{~km} / \mathrm{h}<$ max speed <= $80 \mathrm{~km} / \mathrm{h}), \mathrm{c}$. (max speed $>80 \mathrm{~km} / \mathrm{h}$ )

It can be seen from Figure 16a that for Japan and India the median brake phase duration ( $50^{\text {th }}$ percentile) is almost 3 s , while EU, US and Korean data showed slightly higher average brake phase duration (3.5-4.0 s). These figures are in line with those presented in Chapter 3 (Table 2e) for the urban areas of all regions showing that the majority of short trips with max speed of $60 \mathrm{~km} / \mathrm{h}$ occur in urban areas. Threshold value for the brake duration for short trips with max speed of $60 \mathrm{~km} / \mathrm{h}$ ( $95^{\text {th }}$ percentile) seems to be close to 10 s for all regions except for India ( $\sim 8 \mathrm{~s}$ ).

Regarding the distributions for deceleration phases with max speed between 60 and $80 \mathrm{~km} / \mathrm{h}$ and above $80 \mathrm{~km} / \mathrm{h}$, drivers appear to behave differently depending on the region. For instance, while for max speeds that correspond to rural conditions Japanese and Indian drivers push their brakes in average for $3 \mathrm{~s}\left(50^{\text {th }}\right.$ percentile), drivers from Europe and the US brake in average for about 5 s and 7 s , respectively (Figure 16b). Finally, it is noteworthy that in Asia for short trips with max speeds $>60 \mathrm{~km} / \mathrm{h}$ more than $30 \%$ of the braking events are shorter than 2 s .

Figure 17 shows a comparison of the average curves for Europe with the different maximum speed ranges. It can be seen that for short trips with maximum speed lower than $60 \mathrm{~km} / \mathrm{h}$ (i.e. mostly data from urban areas) and higher than $80 \mathrm{~km} / \mathrm{h}$ (i.e. mostly data from motorways) the median brake phase duration is 3 s , while for medium speeds the average brake duration is almost 4.5 s . These values are in-line with those given for different road categories in Table 2a. Threshold values for the brake duration ( $95^{\text {th }}$ percentile) seem to be close to 9 s for speeds lower than $60 \mathrm{~km} / \mathrm{h}$ and 12 s for higher speeds. In general, brake phase duration longer than 12 s can be considered as "extreme". In all cases more than $20 \%$ of the braking events are shorter than 2 s .

Figure 17: Brake phase duration distributions for short trips with different max speed

### 9.2.2 Brake phase distance distributions

Vehicle specific distance distributions for the different regions and for deceleration phases in short trips with max speed <= $60 \mathrm{~km} / \mathrm{h}$, between 60 and $80 \mathrm{~km} / \mathrm{h}$ and $>80 \mathrm{~km} / \mathrm{h}$ are given in Figure 18. Like in previous cases data for lower speeds exhibited homogeneity for different regions, while for higher speeds Asian data tend to differentiate from European and US data. In general, braking distances longer than 70 m are not very common ( $95^{\text {th }}$ percentile) for urban areas worldwide. In highways the threshold value is between 200-250 m (Figure 18c).

Figure 4: Brake phase distance distributions for the different regions and for different maximum speeds: $a(\max$ speed <= $60 \mathrm{~km} / \mathrm{h}), b(60 \mathrm{~km} / \mathrm{h}<$ max speed <= $80 \mathrm{~km} / \mathrm{h}), c$ (max speed $>80 \mathrm{~km} / \mathrm{h}$ )

Figure 19 shows a comparison of the average curves for the European data for short trips with different maximum speed ranges. The differences among speeds described for all regions are apparent. While the median brake phase distance ( $50^{\text {th }}$ percentile) for the lower maximum speed category is 20 m it goes up to 100 m when the maximum speed category of $>80 \mathrm{~km} / \mathrm{h}$ is examined. Also the "threshold" value of the brake phase distance rises from 70 m to 250 m when going from the lower to the higher maximum speed category.

Figure 19: Brake phase distance distributions for short trips with different max speeds

### 9.2.3 Number of brake phases per km

Table 5 shows the number of brake phases per km distance driven for different regions, road categories and vehicles. From Table 5 it is seen that the median number of braking event per km in Europe, India and the US is approximately 1.5. Higher rates are observed in Korea and Japan. As discussed in a previous chapter almost 1 out of 5 trips in Europe and Japan occur within a creeping situation. This explains the high number of braking events (> 5 braking events $/ \mathrm{km}$ ) found in short trips with max speed of $60 \mathrm{~km} / \mathrm{h}$ in these 2 regions.

| Number of Braking Events per km [\#/km] |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Region | Average | Short Trips with max Speed [km/h] |  |  |  |  |
|  |  | $<=60$ | $\mathbf{6 0 - 8 0}$ | $\mathbf{8 0} \mathbf{- 1 1 0}$ | $>110$ |  |
| Europe | 1.56 | 5.3 | 2.1 | 1.0 | 0.4 |  |
| India Class 1 | 1.36 | 1.7 | 0.5 | 0.0 | 0.0 |  |
| India Class 2 | 1.55 | 3.7 | 1.3 | 0.8 | 0.0 |  |
| India Class 3 | 1.84 | 4.4 | 1.9 | 1.1 | 1.1 |  |
| Japan | 3.00 | 6.1 | 2.1 | 0.7 | 0.4 |  |
| Korea | 2.01 | 4.3 | 1.5 | 0.8 | 0.7 |  |
| USA | 1.37 | 6.4 | 2.4 | 1.3 | 0.3 |  |

Table 5: Number of brake phases per km distance for different regions
Table 6 shows the number of brake phases per km for different regions per road category. In parenthesis where available the percentage of brake phases down to a stop phase with respect to the total number of brake phases is given. Unfortunately, US data came without information regarding the road type, therefore it was not possible to make the calculations.

| Number of Braking Events per km [\#/km] |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| Region | Average | Type of Road |  |  |
|  |  | Urban | Rural | Motorway |
| Europe | 1.56 | $3.8(31.8 \%)$ | $1.0(15.7 \%)$ | $0.2(13.5 \%)$ |
| India Class 1 | 1.36 | 3.2 | 1.6 | 0.0 |
| India Class 2 | 1.55 | 2.3 | 1.5 | 0.8 |
| India Class 3 | 1.84 | 2.8 | 2.1 | 1.0 |
| Japan | 3.00 | $4.5(34.5 \%)$ | $1.3(38.6 \%)$ | $1.2(22.7 \%)$ |
| Korea | 2.01 | $3.6(42.4 \%)$ | $1.4(19.5 \%)$ | $0.7(15.9 \%)$ |
| USA | 1.37 | $*$ | $*$ | $*$ |

Table 6: Number of brake phases per km (\#) and percentage (\%) of brake phases down to a stop phase with respect to the total number of brakes for different regions per road category

Table 6 shows that almost 4 braking events per vehicle per km occur in European urban areas. The median number of braking events per km is higher only in Japan. Almost 1 out of 3 braking events in European urban areas are down to stop phase (31.8\%) with the major part of it being linked to creeping situations. Significantly lower braking rates are observed for rural areas and motorways. Generally higher braking rates both in terms of number of events and percentage of brake phases down to a stop phase are observed in Japan. It seems that the braking behaviour in Japan is different compared to the rest of the world. It is also noteworthy that 1.2 braking events per km occur in Japanese motorways with almost $20 \%$ of these events leading to the immobilization of the vehicle.

## 10 Acceleration distributions for accelerations $\mathbf{>} 0.15 \mathrm{~m} / \mathrm{s}^{\mathbf{2}}$

Figure 20 shows the acceleration distributions for different road categories in Europe (time weighted). Unfortunately these data are not available averaged for other regions worldwide (Asia, USA). However, details regarding other regions can be found in the detailed version of the current report.

Figure 20: Acceleration distributions for road categories in Europe
It is seen from Figure 20 that average accelerations ( $50^{\text {th }}$ percentile) in European urban areas are close to $0.5 \mathrm{~m} / \mathrm{s}^{2}$, while lower values are observed in rural areas and motorways. In urban situations there are plenty of decelerations down to standstill at low speeds with high negative values, while decelerations on motorways are typically related to high vehicle speeds but lower decelerations on average. On the other hand, when investigating
"threshold" values ( $95^{\text {th }}$ percentile) it is observed that accelerations higher than $1.4 \mathrm{~m} / \mathrm{s}^{2}$ can be characterized as "extreme". Finally, it comes out that accelerations higher than $2.0 \mathrm{~m} / \mathrm{s}^{2}$ are very rare in European roads.

## 11 Deceleration distributions for decelerations < -0.15 m/s ${ }^{\mathbf{2}}$

Figure 21 depicts the deceleration distributions for different road categories in Europe. Again this kind of data is not available averaged for other regions worldwide.

Figure 21: Deceleration distributions for road categories in Europe
It is seen from Figure 21 that the median decelerations ( $50^{\text {th }}$ percentile) in European urban areas are close to $-0.6 \mathrm{~m} / \mathrm{s}^{2}$, while lower values are observed in rural areas and motorways (approximately $-0.4 \mathrm{~m} / \mathrm{s}^{2}$ ). "Threshold" values ( $95^{\text {th }}$ percentile) for decelerations in urban and rural areas are close to $-1.7 \mathrm{~m} / \mathrm{s}^{2}$ and can be characterized as "extreme".

## $12 v^{*}$ a negative distributions for $v^{*} a<-1 \mathrm{~m}^{2} / \mathrm{s}^{\mathbf{3}}$

Figure 22a: $v^{*}$ a distributions for vehicle speed classes in Europe

Figure 22b-d: v*a negative distributions for vehicle speed classes: b (India class 1), c (Japan M1), d (Korea)

Figure 22e: $v^{*}$ a negative distributions for vehicle speed classes in USA, Los Angeles
Figure 22 depicts the vehicle speed*deceleration distributions for different maximum speed categories worldwide. These distributions are considered to be indicative for the energy dissipated in the wheel due to a braking event. The median values ( $50^{\text {th }}$ percentile) in the European region range from $3-8 \mathrm{~m}^{2} / \mathrm{s}^{3}$ depending on the speed category examined ( $2.8 \mathrm{~m}^{2} / \mathrm{s}^{3}$ is the averaged value for urban areas). In general, higher maximum speeds result in higher $v^{*}$ a values. Lower median values were observed in India (average values of $1.8-2.5 \mathrm{~m}^{2} / \mathrm{s}^{3}$ depending on the road category), while Korean, Japanese and US data exhibited a significantly wider range of values $\left(3-15 \mathrm{~m}^{2} / \mathrm{s}^{3}\right)$. On the other hand, threshold values for the European dataset range from $4-35 \mathrm{~m}^{2} / \mathrm{s}^{3}$ depending again on the speed category. Threshold values in the US were in some cases as high as $45 \mathrm{~m}^{2} / \mathrm{s}^{3}$.

Table 7 summarizes all the information described in the previous paragraph regarding the $\mathrm{v}^{*}$ a negative distributions for different road categories worldwide. The US data could not be included in this particular part of the analysis because the available data do not allow the split into different road categories (i.e. urban, rural, motorway).

| Region | Road <br> Type |  |  |  |  |  |  |  |  |  | $\mathbf{5 \%}$ | $\mathbf{1 0 \%}$ | $\mathbf{2 5 \%}$ | $\mathbf{5 0 \%}$ | $\mathbf{7 5 \%}$ | $\mathbf{9 0 \%}$ | $\mathbf{9 5 \%}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Motorway | 2.3 | $\mathbf{2 . 7}$ | 3.2 | 5.2 | 9.4 | 15.0 | 19.6 |  |  |  |  |  |  |  |  |  |

|  | Rural | 1.0 | 1.3 | 1.9 | 3.6 | 6.0 | 8.6 | 10.6 |  |  |  |  |  |  |  |  |  |
|  | Urban | 0.4 | 0.7 | 1.3 | 2.8 | 4.9 | 7.0 | 8.5 |  |  |  |  |  |  |  |  |  |

Table 7: Vehicle speed*deceleration distributions for different regions worldwide per road category

## 13 Definition of a typical "journey" in the European region

Figure 23 shows the distribution of the number of short trips driven within a "journey" for different road categories in Europe. The distribution given as averaged refers to the number of stops within the "journey". As a "journey" it is defined the distance and the stop phases from the moment the driver sets the engine on to the moment the vehicle is being parked. These distributions could give some information regarding the conditions under which a typical European journey is executed, meaning how many times the driver has to stop the vehicle due to traffic lights, traffic jams, etc.

The median number of stops within a European Journey ( $50^{\text {th }}$ percentile) resulted to be somewhat more than 4. These stops occur within an average covered distance of approximately 13.2 km . On the other hand, the $95^{\text {th }}$ percentile for the number of stops is 15 . It is characteristics that only very few "journeys" include more than 25 stops.

When the median number of short trips within a "journey" ( $50^{\text {th }}$ percentile) is examined there are significant differences among the 3 road categories. Average number of short trips in urban conditions is approximately 3.5 , while in rural areas and motorways is almost 1 . In urban areas the 3.5 stops occur within an average covered distance of approximately 3.7 km . On the other hand, the $95^{\text {th }}$ percentile for the number of short trips in urban areas is 15 . Lower values are recorded in rural areas and motorways ( 7 and 3 short trips in 56 and 15 km , respectively).

Figure 23: Distribution of the number of short trips per "journey" for different road categories in Europe. The distribution marked as averaged refers to the number of stops within the "journey"

## 14 Annex

Technical data of the vehicles used in the framework of the WLTP database in different regions worldwide are given in Error! Reference source not found.A1 to Error! Reference source not found.A4.
