

# **Mysteries of Interpolation(IP) Method**

**New Issues TF**

Prepared by JAPAN

07~08 March 2018

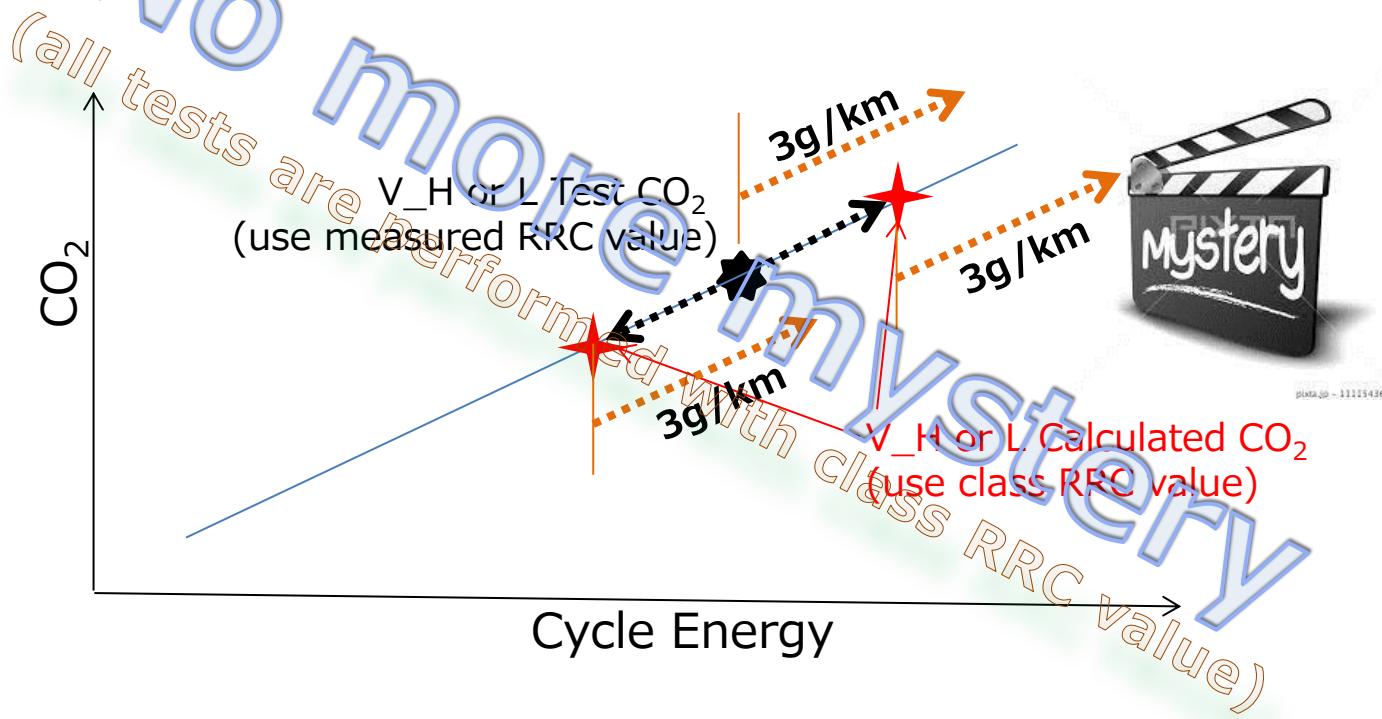

# Mystery #1 ; NO Consistency of Tyre RRC

Possible configurations	RRC		
	Vehicle_H	Individual vehicle	Vehicle_L
1. do not apply IP method	measured value	NA	NA
2. apply IP method	2-1. Same tyre within IPF	class value	
	2-2. Same tyre on vehicle_H and _L but different tyre on individual vehicle		
	2-3. Different tyre on vehicle_H and _L		

**ACTION : make GTR more clear to have same interpretation**

# Mystery #2 ; 3g/km Extension from Cal. ? or Test CO<sub>2</sub> value ?

# Mystery #3 ; how to develop $f_0$ and $f_2$ with fixed $f_1$ ?

GTR describes “applying the least squares regression method”  
(Annex7 3.2.3.2.2.4), however this method may be unpractical.  
(2<sup>nd</sup> order regression with fixed 1<sup>st</sup> order coefficient?)

$$F_{VH} = f_{0,H} + f_{1,H} \times v + f_{2,H} \times v^2$$

$$F_{VL} = f_{0,L} + f_{1,L} \times v + f_{2,L} \times v^2$$

$$\downarrow f_{1,H}$$

pista.jp - 11115436

**Mystery #4 ; adjusted  $f_{0,L}$  and/or  $f_{2,L}$  are bigger than  $f_{0,H}$  and/or  $f_{2,H}$  ?**

**→ Concept of IP method is collapsed !!!**

**Manufacture\_A**

Re-run the road-load test until  $f_{0,H}$  and/or  $f_{2,H}$  are bigger than  $f_{0,L}$  and/or  $f_{2,L}$  ?

Are there any good practical suggestions to eliminate such a ridiculous re-tests ?

pixta.com - 11115436

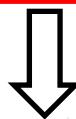

# Mystery #5 ; Huge Error when adjust $f_{1,L}$ to $f_{1,H}$

## 3.2.3.2.2.4. Calculation of road load for individual vehicles

Possible  $f_1$  variability of same type of vehicle configurations

Model	A	B	C	D	E	F	G	H
AVE	0.3958	0.2974	0.1847	-0.2831	-0.0146	-0.1222	0.2906	0.8777
MAX	0.5976	0.4073	0.3185	0.0198	0.3117	0.2539	0.9802	1.0563
MIN	0.2013	0.0730	-0.0304	-0.5555	-0.1587	-0.4968	-0.0001	0.5113
MAX-MIN	0.3963	0.3343	0.3489	0.5753	0.4704	0.7507	0.9803	0.5450
$\sigma$	0.1545	0.1400	0.1499	0.2376	0.2191	0.3108	0.4621	0.2475
3σ片側	0.4635	0.4201	0.4496	0.7127	0.6574	0.9324	1.3863	0.7426
±3σ両側	0.9269	0.8403	0.8992	1.4254	1.3147	1.8648	2.7726	1.4853

case study

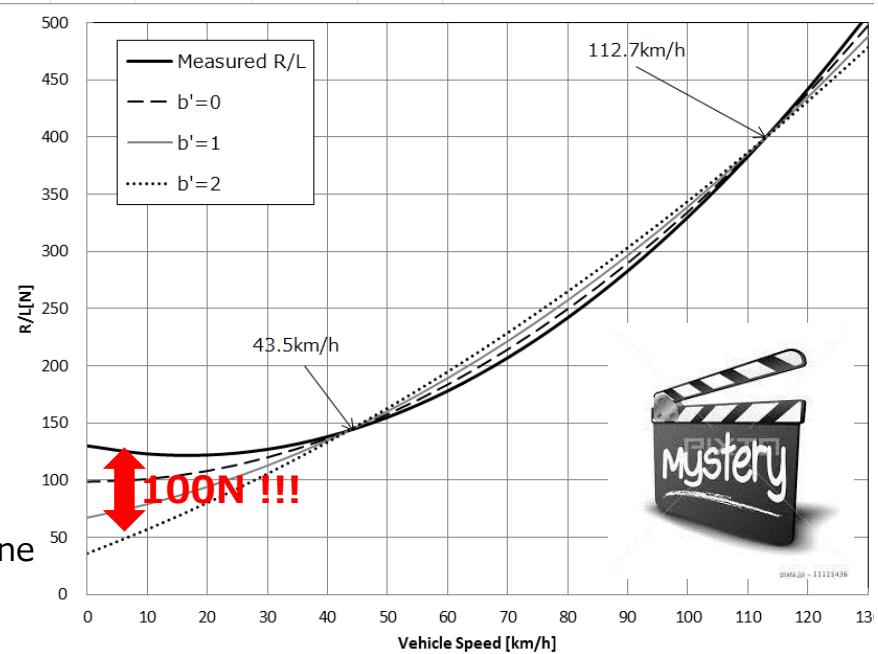

R/L	measured R/L	b'=0	b'=1	b'=2	= $f_{1,H}$
$f_{2,L}$ a=	0.03000	0.02360	0.01720	0.01080	
$f_{1,L}$ b=	-1.0000	0.0000	1.0000	2.0000	
$f_{0,L}$ c=	130.0	98.63	67.3	35.9	

However, cycle energy demand is almost identical to original one

→ calculated individual vehicle CO<sub>2</sub> is OK. **BUT ....**

# Complicated!! but NECESSARY !!

STEP1 : change  $f_{1,L}$  to  $f_{1,H}$  and derive new  $f^*_{0,L}$  and  $f^*_{2,L}$  (follow GTR)

STEP2 : calculate cycle energy demand of  $V_H$  or  $V_L$  (follow GTR)

In case that physical test is conducted on the individual vehicle and

if [ \*\*\*\* \* ]

<< applicable threshold is under the discussion (or option) >>

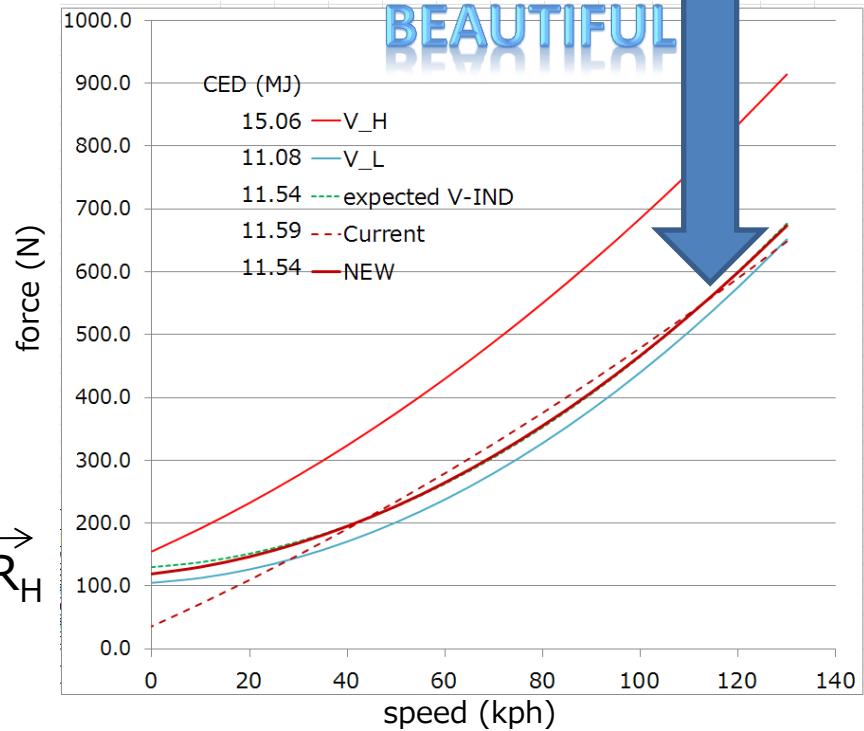

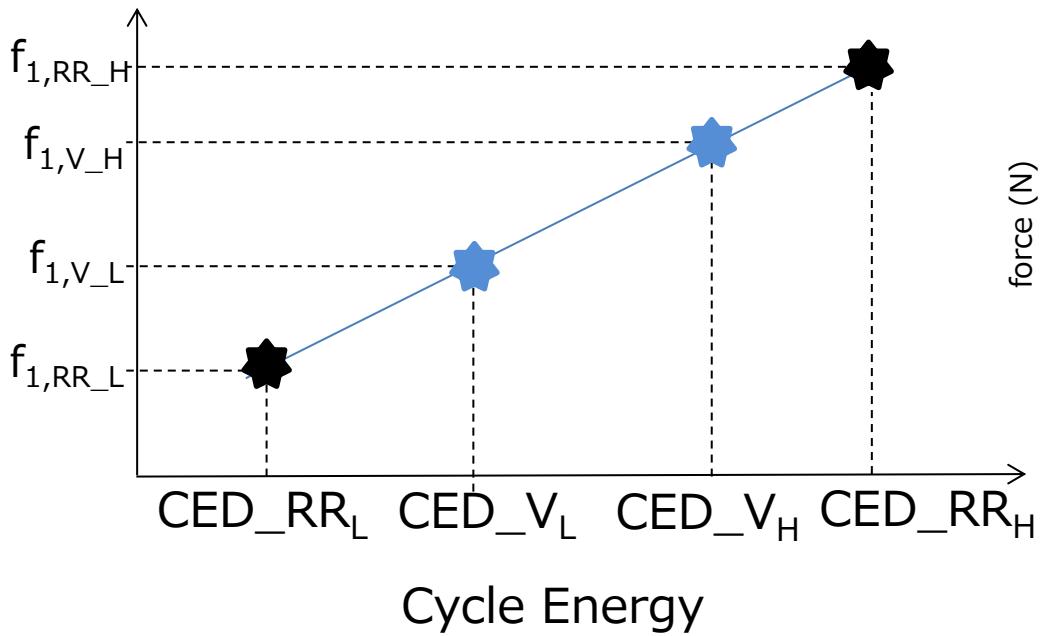

STEP3 : re-adjust  $f_{1,y \text{ H or L}}$  according to the next slide formula

STEP4 : then derive  $f_0$ ,  $f_2$  and run the test

STEP5 : for CO<sub>2</sub> determination, cycle energy demand shall be calculated

by using original  $f_{0,1,2}$  to avoid unnecessary burden.

$$f_{1,V_H \text{ or } L} = \frac{(CED_{V_H \text{ or } L} - CED_{RR_L}) * f_{1,RR_H} + (CED_{RR_H} - CED_{V_H \text{ or } L}) * f_{1,RR_L}}{(CED_{RR_H} - CED_{RR_L})}$$
