Progress on thermal propagation testing

Slide #4

It is OICA's understanding that the IWG is to complete its work on Phase 2, including finalization of proposed regulatory text, by the end of 2020.

- 1) How much of the research work described on this slide will be completed in time to support this timeline?
- 2) When is the 'Pack, Vehicle' work estimated to be complete?

Electrolyte leakage/venting verification

Slide #41

Free liquid electrolyte -toxicity

Solvent	Volume of evaporated solvent*, ml	
	PAC-2 level	PAC-3 level
Diethyl carbonate (DEC), CAS # 105-58-8	1.4	21.5
Dimethyl carbonate (DMC), CAS # 616-38-6	25	149
Acetonitrile (AN), CAS # 75-05-8	42	86

* Volume, solvent evaporates into, is defined as vehicle + 1-m clearance

PAC stands for **Protective Action Criteria**

PAC-2: Irreversible or other serious health effects that could impair the ability to

PAC-3: Life-threatening health effects

Can be
achieved from
1 cell only

N.P. Lebedeva, L. Boon-Brett, Considerations on the Chemical Toxicity of Contemporary Li-Ion Battery Electrolytes and Their Components, Journal of the Electrochemical Society 163 (2016) A821

What value (ppm, mg/m³) was used to determine the DEC volume calculation?

According to current (Revision 29) data (<https://sp.eota.energy.gov/pac/Search/Reports/975>)

- PAC-2 = 140 ppm or 650 mg/m³
- PAC-3 = 810 ppm or 3900 mg/m³

[The indicated reference [1] shows significantly different values. Perhaps an update was published?]

Using the current PAC published specific gravity (0.9752) and 61.5 m³ space, this would require ~41 ml of DEC to achieve PAC-2 levels.

According to the PAC website (<https://sp.eota.energy.gov/pac/TeelDef>), the values are based on a one hour exposure at the indicated level of concentration.

- In an open environment, the most probable condition for an automotive application, any concentrations would quickly dissipate.
- In an enclosed environment, an air exchange rate exists which would reduce the concentration over time. Air exchange rates of 0.03 to 0.3 exchanges per hour are representative of “extremely tight” to “ventilated” conditions (SAE J2578, 5.2.1, 5.2.2).

Electrolyte leakage/venting verification

Slide #42 – first bullet

Free liquid electrolyte - conclusions

- Li-ion battery cells can contain free liquid electrolyte in amounts sufficient for the formation of potentially toxic atmosphere in enclosed spaces after a release of electrolyte from a single battery cell.
- It is especially alarming that Li-ion cells containing appreciable amount of free liquid electrolyte are used in mass-production PHEVs and BEVs, which are on the EU market since 2013 and 2010, and which belong to the top-10 most sold electric vehicle models in the EU.
- Release of the contained free liquid electrolyte represents the best case scenario as its amount corresponds to the minimum amount of electrolyte that can be released from a battery cell when the integrity of the cell casing is compromised.

42

The stated conclusion requires all free electrolyte to exit the cell and evaporate simultaneously.

- What evidence do you have that this would occur in an actual battery?
- For a realistic, in-vehicle leakage condition, what is the estimated leakage rate of liquid electrolyte out of a cell? How was this determined?

The functional purpose of free electrolyte inside of a cell is to support longer life. As cells age, electrolyte is consumed.

- For the single cell type in the reference [2], an average of 95% of the free electrolyte was gone at ~50-75% of expected useful life.
- The stated conclusion is only valid at the time a cell is new, which is also the time that it would be least likely to leak.

2. N. P. Lebedeva, F. Di Persio, T. Kosmidou, D. Dams, A. Pfrang, A. Kersys, L. Boon-Brett, Amount of Free Liquid Electrolyte in Commercial Large Format Prismatic Li-Ion Battery Cells, Journal of the Electrochemical Society 166 (2019) A779-A786.

Electrolyte leakage/venting verification

Slide #42 – second bullet

Free liquid electrolyte - conclusions

- Li-ion battery cells can contain free liquid electrolyte in amounts sufficient for the formation of potentially toxic atmosphere in enclosed spaces after a release of electrolyte from a single battery cell.
- It is especially alarming that Li-ion cells containing appreciable amount of free liquid electrolyte are used in mass-production PHEVs and BEVs, which are on the EU market since 2013 and 2010, and which belong to the top-10 most sold electric vehicle models in the EU.
- Release of the contained free liquid electrolyte represents the best case scenario as its amount corresponds to the minimum amount of electrolyte that can be released from a battery cell when the integrity of the cell casing is compromised.

42

Given the duration of the indicated cells in the market, is there any evidence that the speculated concern regarding electrolyte leakage and toxic effects has actually occurred in vehicles in the field?
